

10th May : Styling in Mobile Dev + Jaani

1. Safe Area View

⇒ Screen height - status bar - home bar = usable screen

⇒ SafeAreaView is deprecated in react-native, even if you use it, will work on iOS 11+ and not on android.

⇒ To use, import `{SafeAreaView}` from `"react-native-safe-area-context"`;

⇒ To use wrap it inside `<SafeAreaView>`

Use SafeArea Insets

Is a hook from `react-native-safe-area-context`.

⇒ It gives us more control, we can give custom spacing, animations, sticky headers etc.

Code: `const HomeScreen = () => {
 const insets = useSafeAreaInsets();
 log(Insets);
 return (
 <View style = { {
 flex: 1,
 paddingTop: insets.top,
 paddingBottom: insets.bottom,
 } }
 >
 <Text> Home Screen </Text>
 </View>
);
};`

If you want your **StatusBar** in black colour, use code:
`<StatusBar barStyle = { "dark-content" } />`

Styling

Code:
`import React from "react"
import { StyleSheet, Text, View } from "react-native"
const HomeScreen = () => {
 return (
 <View style = { styles.card } >
 <Text style = { styles.title } > Home Screen </Text>
 <Text style = { styles.subtitle } > hello </Text>
 </View>
);
};`

```
export default HomeScreen;
```

```
const styles = StyleSheet.create({  
  card: {  
    backgroundColor: "white",  
    borderRadius: 16,  
    elevation: 4 } → for shadow  
  },  
});
```

Note : Don't keep the style object inside the component, ~~as~~ then after every render creates a new object in memory, we don't want that to happen. So we try keeping it outside to keep code efficient and cleaner.

Expo has its own status bar.

→ cmd: npx expo install expo-status-bar

± This is used to control phone status bar.

Code in index.tsx

```
import React from "react";  
import { StyleSheet, Text, View } from "react-native";  
const HomeScreen = () => {  
  const isActive = true;  
  return (  
    <View style={styles.container}>  
      <View style={styles.button, isActive ? styles.activeBtn}>  
        <Text style={styles.buttonText} />  
      </View>  
    </View>  
  );  
};
```

```
export default HomeScreen;

const styles = StyleSheet.create({
  container: { flex: 1, justifyContent: 'center',
    alignItems: 'center' },
```

```
    button: {
      paddingVertical: 12,
```

```
      activeButton: {
```

```
        backgroundColor: '#6C63FF' // → override
                                     button color
                                     when btn
```

```
        buttonText: 'is active'
      }
    },
```

3.

StyleSheet.compose() to merge two styles together

→ mostly used in →

1. internal optimization

2. conditional merging etc

StyleSheet.flatten() converts multiple styles into ONE plain JS object.

Difference b/w **.compose** and **.flatten** →

.compose() is used for combining styles efficiently. It returns a result styles React Native can use directly. Usually used programmatically.

while

.flatten converts styles into real JS objects.

useWindowDimension is a React native hook that gives the current screen size dynamically. [5]
This updates on screen rotation, split screen etc

⇒ Mini Project

⇒ Import React from "react"

```
import { StyleSheet, Text, View, useWindowDimension } from  
import * as ScreenOrientation from "expo-screen-orientation" | "react-native"
```

```
const HomeScreen = () => {
```

```
  const { height, width } = useWindowDimensions()
```

```
  const isTablet = width >= 768,
```

```
  const isLandscape = width > height;
```

```
  const lockLandscape = async () => {
```

```
    await ScreenOrientation.lockAsync
```

```
    ScreenOrientation.OrientationLock.LANDSCAPE,
```

```
  );
```

```
};
```

// Same for portrait;

Read about font scale and scale.

Color-Scheme using useColorScheme

```
⇒ const HomeScreen = () => {
```

```
  const systemScheme = useColorScheme();
```

```
  const [manualDark, setManualDark] = useState<boolean>  
    (null);
```

```

const isDark = manualDark !== null ? manualDark :
  (systemScheme === "dark")
const theme = isDark ? themes.dark : themes.light
log(systemTheme);
return (
  <View style = {{ styles.container, { backgroundColor: theme.background } }}
  </View>

```

6

To put it inside SafeAreaView

To change theme of statusBar:

```

<StatusBar style = { manualDark ? "light" : "dark" } />

```

Assignment: Build a notes App Screens (No navigation)

View 1

- All notes in a Flatlist
- Each note card show title, preview date

View 2

- Text Input for title etc

more can be found on the tldraw
